6.1 ENTHALPIES AND GIBBS ENERGIES OF FORMATION, ENTROPIES, AND HEAT CAPACITIES

The tables in this section contain values of the enthalpy and Gibbs energy of formation, entropy, and heat capacity at 298.15 K (25°C). No values are given in these tables for metal alloys or other solid solutions, for fused salts, or for substances of undefined chemical composition.

The physical state of each substance is indicated in the column headed “State” as crystalline solid (c), liquid (lq), or gaseous (g). Solutions in water are listed as aqueous (aq).

The values of the thermodynamic properties of the pure substances given in these tables are, for the substances in their standard states, defined as follows: For a pure solid or liquid, the standard state is the substance in the condensed phase under a pressure of 1 atm (101 325 Pa). For a gas, the standard state is the hypothetical ideal gas at unit fugacity, in which state the enthalpy is that of the real gas at the same temperature and at zero pressure.

The values of $\Delta_f H^\circ$ and $\Delta_f G^\circ$ that are given in the tables represent the change in the appropriate thermodynamic quantity when one mole of the substance in its standard state is formed, isothermally at the indicated temperature, from the elements, each in its appropriate standard reference state. The standard reference state at 25°C for each element has been chosen to be the standard state that is thermodynamically stable at 25°C and 1 atm pressure. The standard reference states are indicated in the tables by the fact that the values of $\Delta_f H^\circ$ and $\Delta_f G^\circ$ are exactly zero.

The values of S° represent the virtual or “thermal” entropy of the substance in the standard state at 298.15 K (25°C), omitting contributions from nuclear spins. Isotope mixing effects are also excluded except in the case of the ^1H — ^2H system.

Solutions in water are designated as aqueous, and the concentration of the solution is expressed in terms of the number of moles of solvent associated with 1 mol of the solute. If no concentration is indicated, the solution is assumed to be dilute. The standard state for a solute in aqueous solution is taken as the hypothetical ideal solution of unit molality (indicated as std. state or ss). In this state

the partial molal enthalpy and the heat capacity of the solute are the same as in the infinitely dilute real solution.

For some tables the uncertainty of entries is indicated within parentheses immediately following the value; viz., an entry 34.5(4) implies 34.5 ± 0.4 and an entry 34.5(12) implies 34.5 ± 1.2 .

6.1.1 Some Thermodynamic Relations

6.1.1.1 Enthalpy of Formation. Once standard enthalpies are assigned to the elements, it is possible to determine standard enthalpies for compounds. For the reaction:

Since the elements are in their standard states, the enthalpy change for the reaction is equal to the standard enthalpy of CO_2 less the standard enthalpies of C and O_2 , which are zero in each instance. Thus,

$$\Delta_f H^\circ = -393.51 - 0 - 0 = -393.51 \text{ kJ} \quad (6.2)$$

Tables of enthalpies, such as Tables 6.1 and 6.3, can be used to determine the enthalpy for any reaction at 1 atm and 298.15 K involving the elements and any of the compounds appearing in the tables.

The solution of 1 mole of HCl gas in a large amount of water (infinitely dilute real solution) is represented by:

The heat evolved in the reaction is $\Delta H^\circ = -74.84$ kJ. With the value of $\Delta_f H^\circ$ from Table 6.3, one has for the reaction:

$$\Delta_f H^\circ = \Delta_f H^\circ[\text{H}^+(\text{aq})] + \Delta_f H^\circ[\text{Cl}^-(\text{aq})] - \Delta_f H^\circ[\text{HCl(g)}] \quad (6.4)$$

for the standard enthalpy of formation of the pair of ions H^+ and Cl^- in aqueous solution (standard state, $m = 1$). To obtain the $\Delta_f H^\circ$ values for individual ions, the enthalpy of formation of $\text{H}^+(\text{aq})$ is arbitrarily assigned the value zero at 298.15 K. Thus, from Eq. (6.4):

$$\Delta_f H^\circ[\text{Cl}^-(\text{aq})] = -74.84 + (-92.31) = -167.15 \text{ kJ}$$

With similar data from Tables 6.1 and 6.3, the enthalpies of formation of other ions can be determined. Thus, from the $\Delta_f H^\circ[\text{KCl(aq, std. state, } m = 1 \text{ or aq, ss)}]$ of -419.53 kJ and the foregoing value for $\Delta_f H^\circ[\text{Cl}^-(\text{aq, ss})]$:

$$\begin{aligned} \Delta_f H^\circ[\text{K}^+(\text{aq, ss})] &= \Delta_f H^\circ[\text{KCl(aq, ss)}] - \Delta_f H^\circ[\text{Cl}^-(\text{aq, ss})] \\ &= -419.53 - (-167.15) = -252.38 \text{ kJ} \end{aligned} \quad (6.5)$$

6.1.1.2 Enthalpy of Vaporization (or Sublimation) When the pressure of the vapor in equilibrium with a liquid reaches 1 atm, the liquid boils and is completely converted to vapor on absorption of the enthalpy of vaporization ΔHv at the normal boiling point T_b . A rough empirical relationship between the normal boiling point and the enthalpy of vaporization (*Trouton's rule*) is:

$$\frac{\Delta Hv}{T_b} = 88 \text{ J} \cdot \text{mol}^{-1} \cdot \text{K}^{-1} \quad (6.6)$$

It is best applied to nonpolar liquids which form unassociated vapors.

To a first approximation, the enthalpy of sublimation ΔH_s at constant temperature is:

$$\Delta H_s = \Delta H_m + \Delta Hv \quad (6.7)$$

where ΔH_m is the enthalpy of melting.

The *Clapeyron* equation expresses the dynamic equilibrium existing between the vapor and the condensed phase of a pure substance:

$$\frac{dP}{dT} = \frac{\Delta Hv}{T\Delta V} \quad (6.8)$$

where ΔV is the volume increment between the vapor phase and the condensed phase. If the condensed phase is solid, the enthalpy increment is that of sublimation.

Substitution of $V = RT/P$ into the foregoing equation and rearranging gives the *Clausius-Clapeyron* equation,

$$\frac{dP}{P dT} = \frac{\Delta Hv}{RT^2} \quad (6.9)$$

or

$$\Delta Hv = -R \frac{d(\ln P)}{1/T} \quad (6.10)$$

which may be used for calculating the enthalpy of vaporization of any compound provided its boiling point at any pressure is known. If an Antoine equation is available (such as Eq. (5.1), page 5.30), differentiation and insertion into the foregoing equation gives:

$$\Delta Hv = \frac{4.5757T^2B}{(T + C - 273.15)^2} \quad (6.11)$$

Inclusion of a compressibility factor into the foregoing equation, as suggested by the *Haggenmacher* equation improves the estimate of ΔHv :

$$\Delta Hv = \frac{RT^2}{P} \left(\frac{dP}{dT} \right) \left(1 - \frac{T_c^3 P}{T^3 P_c} \right)^{1/2} \quad (6.12)$$

where T_c and P_c are critical constants (Table 6.5). Although critical constants may be unknown, the compressibility factor is very nearly constant for all compounds belonging to the same family, and an estimate can be deduced from a related compound whose critical constants are available.

6.1.1.3 Heat Capacity (or Specific Heat) The temperature dependence of the heat capacity is complex. If the temperature range is restricted, the heat capacity of any phase may be represented adequately by an expression such as:

$$C_p = a + bT + cT^2 \quad (6.13)$$

in which a , b , and c are empirical constants. These constants may be evaluated by taking three pieces of data: $(T_1, C_{p,1})$, $(T_2, C_{p,2})$, and $(T_3, C_{p,3})$, and substituting in the following expressions:

$$\frac{C_{p,1}}{(T_1 - T_2)(T_1 - T_3)} + \frac{C_{p,2}}{(T_2 - T_1)(T_2 - T_3)} + \frac{C_{p,3}}{(T_3 - T_2)(T_3 - T_1)} = c \quad (6.14)$$

$$\frac{C_{p,1} - C_{p,2}}{T_1 - T_2} - [(T_1 + T_2)c] = b \quad (6.15)$$

$$(C_{p,1} - bT_1) - cT_1^2 = a \quad (6.16)$$

Smoothed data presented at rounded temperatures, such as are available in Tables 6.2 and 6.4, plus the C_p° values at 298 K listed in Table 6.1 and 6.3, are especially suitable for substitution in the foregoing parabolic equations. The use of such a parabolic fit is appropriate for interpolation, but data extrapolated outside the original temperature range should not be sought.

6.1.1.4 Enthalpy of a System The enthalpy increment of a system over the interval of temperature from T_1 to T_2 , under the constraint of constant pressure, is given by the expression:

$$H_2 - H_1 = \int_{T_1}^{T_2} C_p dT \quad (6.17)$$

The enthalpy over a temperature range that includes phase transitions, melting, and vaporization, is represented by:

$$\begin{aligned} H_2 - H_1 &= \int_{T_1}^{T_2} C_p(c,\text{II}) dT + \Delta H_t + \int_{T_1}^{T_m} C_p(c,\text{I}) dT + \Delta H_m \\ &\quad + \int_{T_m}^{T_b} C_p(1\text{q}) dT + \Delta H_v + \int_{T_b}^{T_2} C_p(g) dT \end{aligned} \quad (6.18)$$

Integration of heat capacities, as expressed by Eq. (6.13), leads to:

$$\Delta H = a(T_2 - T_1) + \frac{b(T_2^2 - T_1^2)}{2} + \frac{c(T_2^3 - T_1^3)}{3} \quad (6.19)$$

6.1.1.5 Entropy In the physical change of state,

$$\Delta S_m = \frac{\Delta H_m}{T_m} \quad (6.20)$$

is the entropy of melting (or fusion),

$$\Delta S_v = \frac{\Delta H_v}{T_b} \quad (6.21)$$

is the entropy of vaporization, and

$$\Delta S_s = \frac{\Delta H_s}{T_s} \quad (6.22)$$

is the entropy of sublimation.

A general expression for the entropy of a system, involving any phase transitions, is

$$\begin{aligned} S_2 - S_1 = & \int_{T_1}^{T_f} \frac{C_p(c,\text{II}) \, dT}{T} + \frac{\Delta H_t}{T} + \int_{T_b}^{T_m} \frac{C_p(c,\text{I}) \, dT}{T} + \frac{\Delta H_m}{T} \\ & + \int_{T_m}^{T_b} \frac{C_p(1\text{q}) \, dT}{T} + \frac{\Delta H_v}{T} + \int_{T_b}^{T_f} \frac{C_p(\text{g}) \, dT}{T} \end{aligned} \quad (6.23)$$

If C_p is independent of temperature,

$$\Delta S = C_p(\ln T_2 - \ln T_1) = 2.303 C_p \log \frac{T_2}{T_1} \quad (6.24)$$

If the heat capacities change with temperature, an empirical equation like Eq. (6.13) may be inserted in Eq. (6.23) before integration. Usually the integration is performed graphically from a plot of either C_p/T versus T or C_p versus $\ln T$.

6.2 CRITICAL PHENOMENA

The *critical temperature*, T_c , of a gas is the temperature above which the gas cannot be liquefied no matter how high the pressure.

The *critical pressure*, P_c , is the lowest pressure which will liquefy the gas at its critical temperature.

The *critical volume*, V_c , is the volume of 1 mol at the critical temperature and the critical pressure. It can be computed from the critical density, ρ_c , as follows:

$$\frac{\text{Molecular weight (in g} \cdot \text{mol}^{-1})}{\rho_c \text{ (in g} \cdot \text{cm}^{-3})} = V_c \text{ (in cm}^3 \cdot \text{mol}^{-1})$$

The critical pressure, critical molar volume, and critical temperature are the values of the pressure, molar volume, and thermodynamic temperature at which the densities of coexisting liquid and gaseous phases just become identical. At this critical point, the *critical compressibility factor*, Z_c , is:

$$Z_c = \frac{P_c V_c}{R T_c}$$
